# Exploring how moral intelligence influences the enhancement of psychological resilience among Saudi university students: A case study at King Faisal university

Hussam K. Aldawsari

Department of Psychology, College of Education, King Faisal University, Al-Ahsa 31982, Saudi Arabia.

(Email: haldawsari@kfu.edu.sa)

#### Abstract

Student success in academic and social challenges depends on their possession of moral intelligence together with psychological resilience. The research reveals that moral intelligence plays a fundamental role in building psychological resilience for students attending King Faisal University in Saudi Arabia. The researchers measured moral intelligence through two scales on 386 students at King Faisal University, along with psychological resilience and its 4 axes. Moral intelligence scores for the research sample were found to be average based on measurements, while participants displayed stronger performance in conscientiousness and tolerance but weaker aspects in respect. Psychological resilience levels were moderate, while religious values received superior results, but social support proved quite weak. Females outperformed males in justice measures, although males demonstrated greater competence when it came to social abilities. The research findings establish that psychological resilience tightly matches with moral intelligence levels because religious commitment along with spiritual beliefs boost stress management abilities. Interventions need specific strategies in order to support respect for development and social support enhancement. Further research must analyze how these effects maintain their durability and should focus on various population groups in multiple settings. Studies based on this research will help scholars analyze moral intelligence development through different academic levels while demonstrating culture and subject-specific analysis.

Keywords: Moral intelligence, Psychological resilience, Religious values, Saudi culture, University students.

#### 1. Introduction

Modern society depends on universities to develop students' intellectual abilities by teaching them psychological and moral conduct. Moral intelligence maintains substantial importance because it affects individual conduct and societal welfare [1]. The discernment between right and wrong and ethical principal application constitutes moral intelligence, which includes empathy along with conscience and self-control and shows respect and tolerance and promotes justice [2-4]. The field of healthcare depends on moral intelligence because it directly affects professional competence and the quality of patient care provided [3, 5]. The research proves that moral intelligence strengthens student grades inside schools while promoting a decreased sense of academic entitlement among young high school students [6]. Moral intelligence must undergo reactualization through training and virtue development for building a civilized society, specifically during globalization [2]. Moral intelligence is essential for personal development and resilience since it helps people tackle ethical issues successfully while making positive contributions to their communities [4].

The fundamental construct of positive psychology known as psychological resilience exists as the process of adapting to hardships, which boosts mental health while developing better methods of coping [7]. Psychological resilience represents the human ability to convert negative challenges into positive outcomes, which fortifies personal development and psychological stability [8]. Psychological resilience includes personal attributes such as self-efficacy and optimism as well as social aspects that include family assistance and community support services [9]. Creative expression works as a coping method during stressful situations, according to research that helps foster resilience in individuals [7]. Despite ongoing economic difficulties, families can harness resilience through socio-economic policies that provide Medicaid expansion together with childcare subsidies [10]. Viewing resilience through complex systems science demonstrates its evolutionary qualities because it illustrates how individual characteristics merge with external factors to form reactions to difficult situations [11].

Research indicates that moral intelligence, together with psychological resilience, shows crucial connections across different environments when facing adverse circumstances. The combination of advanced moral intelligence creates strengthened emotional steadiness and interpersonal capabilities that professionals need to manage tough times [12, 13]. Emotional stability enables individuals to regulate their emotions through adaptive techniques, and social skills help them develop friendships that enhance their resilience capability [13]. The combination of high moral intelligence and psychological resilience leads to decreased stress and improved emotional well-being in people, according to research [14, 15]. Similarly, psychological resilience plays a critical role in helping individuals overcome difficulties and thrive despite obstacles [16].

Studies demonstrate moral intelligence serves as a major factor in creating better psychological resilience abilities. The research conducted by Wu, et al. [17] showed psychological resilience maintained positive correlations with coping strategies of Chinese undergraduate students between variables.

The inclusion of moral intelligence into educational structures presents itself as a key method for developing adaptable and hypergrowth behaviors within the university student population. Bursztyn [18] argues that improving moral intelligence creates better relationships and adaptability skills vital for successful learning environments. Student ideological and ethical qualities improve substantially when receiving positive moral education, according to Zhou and Hu (2020), because it builds social responsibility. The Oxford Global Leadership Initiative from Brooks, et al. [19] presents an operational framework that demonstrates methods for universities to establish ethical leadership development at various student population levels. Higher education institutions introduce programs to tackle the rising necessity of moral education, which prepares students to handle complicated social obstacles. Altan [20] supports the integration of moral intelligence throughout regular curriculum instead of separating it into specialized courses because it develops students and educators for social justice advocacy and enhanced societal systems. According to Cujilan, et al. [21] intrapersonal intelligence demonstrates strong relationships towards academic success and adaptive abilities. The research demonstrates the need to build educational systems that develop moral factors alongside intrapersonal capacities to support current learning needs. Multiple research studies suggest implementing comprehensive educational methods that combine ethical development with social growth and personal development for creating resilient graduates who will advance sustainable development.

According to Muhammadaly, et al. [22] the integration of moral intelligence and wisdom needs to be present in educational curricula across general schools through higher education. The study by Gonţa, et al. [23] recommends schools improve their tolerance-building activities and recommends additional tests between different educational levels to verify these approaches. The authors of Romzi, et al. [24] stress that investigations should connect moral intelligence to psychological stress and social competence levels while urging institutions to place moral value development at the forefront of program execution. According to Sofiani, et al. [25] Islamic education provides a complete educational system, which shows how moral instruction within curriculums develops individuals who manage their personal commitments with their social duties. Research findings by Fitria, et al. [26] support the notion that value-driven education remains essential to develop students' ethical and moral understanding, which leads to enhanced life success in personal and social domains. The researchers combine their work to support educational reforms that make moral development the fundamental basis for student development alongside social sustainability.

The present research evaluates moral intelligence together with psychological resilience among King Faisal University students, with a focus on gender and the college-related differences in these variables. This research investigates the relationship's nature and strength between moral intelligence and psychological resilience alongside gender and the college-based analysis of these constructions. The research demonstrates whether gender and the college create differences in the moral intelligence assessment results obtained from male and female students. To identify if gender creates different

levels of psychological resilience among students. This research fills a knowledge gap about the connection of ethical intelligence to psychological resilience through a study of Saudi Arabian university students. The research value stems from its investigation of neglected Saudi educational factors, which enables the creation of personalized programs leading to stronger ethical values in university students.

#### 2. Materials and Methods

### 2.1. Study Participants

The sample utilized for this research included 386 undergraduate students who were enrolled in King Faisal University Saudi Arabian Colleges, among which 222 were female students and 164 were male. All participants fell within the age range of 19 to 21 years. The researcher determined the sample size by using Thompson [27] formula for statistical validity at a 95% confidence level (Z = 1.96) for a target population of 386 undergraduate students. This research used non-probability sampling techniques to choose its participants. Table 1 shows how the study participants distributed among the investigated independent variables and presents their demographic breakdown.

Participants at King Faisal University received approval to join the study after giving their consent for the research project. The university granted ethical approval through its ethics committee (CEC Law No. 18-23), which followed Declaration of World Medical Association [28] principles. Switched research assistants delivered the scales through university locations for participants who needed clarification as part of their methodological preparation. Data collection occurred throughout an academic year through systematic distribution of scales to protect both participant routines and achieve scale compliance. The designed methodology prioritized transparency and confidentiality together with participant autonomy as required by ethical standards for human research.

**Table 1.** Distribution of sample individuals according to independent variables.

Variables		Number	Percentage
Gender	Male	164	42.49%
	Female	222	57.51%
C-11	Scientific Colleges	189	49.96%
College	Humanities Colleges	197	51.04%

#### 2.2. Instrument

The research relied on the Moral Intelligence Scale [6, 20] along with the Psychological Resilience Scale [16, 17, 29] that the researcher developed as their research instrument. The tool received expert feedback from five individuals, and the reliability tests yielded data for calculating Cronbach's alpha together with exploration factor analysis results. The Moral Intelligence Scale included 65 items throughout its measurement portion. The study group reviewed and assessed the items along with the phrases in the scale; after the experts' feedback, five items were eliminated, which left the scale divided into six axes containing sixty items: 10 items in empathy and another 10 items in respect. In comparison, self-control consisted of ten items, conscience with ten items, tolerance with ten items, and justice with ten items (see Appendix A). The researchers utilized Pearson's correlation coefficient to assess scale internal consistency; the first axis correlation coefficients spanned from (0.448-0.679), while the second axis values fell between (0.542-0.711), and the third axis had a range of (0.584-0.830), with the fourth axis values between (0.436-0.741) and the fifth axis (0.477-0.763), whereas the sixth axis values were (0.532-0.655). For this study, the researcher measured the correlation coefficients linking each axis to the total scale score as (0.751 - 0.822 - 0.836 - 0.792 - 0.811 -0.783). The research used the psychological resilience scale, which consisted of 42 items, after expert review of its phrases with three added items (45) items. The scale developed four axes ranging from social support (9) through personal competence (16) to social and family competence (11) and value and religious structure (9) (see Appendix B).

The researchers applied Pearson's correlation coefficient to measure scale internal consistency through the first axis values between (0.532 and 0.701), while the second axis values varied between (0.554 and 0.805), the third axis between (0.577 and 0.758), and the fourth axis between (0.548 and 0.810). The research study revealed correlation coefficient values between 0.801 and 0.761 and 0.853 and 0.775 from the total scores for each axis. The respondents evaluated all scale items through a five-point Likert-type scale anchored strongly does not apply (1) and strongly applies (5). The moral intelligence scale obtained a correlation coefficient value of 0.815. The analysis indicated that the psychological resilience scale reached a correlation coefficient value of 0.749. The study verified statistical importance at P < 0.01 for every variable to demonstrate the sub-items and the entire scale maintains strong internal consistency with their dimensions. Cronbach's alpha coefficients served to prove stability for both the moral intelligence scale and psychological resilience scale in the research. The moral intelligence scale demonstrated exceptional stability level based on its stability coefficient rate, which spanned between (0.776) and (0.885). The values on the psychological resilience scale fell between 0.718 and 0.862. Points from 1 = Never to 5 = Always on the responses of the participants.

# 2.3. Questionnaire Distribution

The researcher created the scales through Google Drive software tools. The King Faisal University in Al-Ahsa established joint efforts to find suitable distribution channels for their student population. The researcher made a formal introduction and then received authorization to give the scales to students. Students received access to those scales at the beginning of the second semester during 2024-2025. Google Drive provided an automated way to collect responses directly

while creating electronic tables that researchers could use for analysis. The period for scale distribution and student survey collection ran between January 14 and February 19, 2025. During the pre-research briefing, participants learned about the whole scope of the study and associated risks within ethical frameworks while receiving reassurance that research data served only academic purposes, and their personal information remained strictly private. Each participant provided authorization through voluntary consent paperwork before agreeing to maintain research guidelines throughout the study. The research protocol upholds ethical standards and protects participant well-being by minimizing potential risks, beginning with the first assessment phase of the study until completion.

#### 2.4. Statistical Analysis

Analysis of obtained survey data used Statistical Package and Social Science (SPSS) tool version 26. A detailed descriptive analysis of the dataset proceeded through standard deviation and mean computation and use of percentages and chi-square tests and Cronbach's alpha score interpretation. The use of IBM Corporation's SPSS 26 statistical social science software during analysis enhanced the result's credibility because this program is recognized widely within the field. The findings gained validity from p<0.05 serving as the set statistical importance threshold, which validated both the research study and its overall methodological quality. The response scores consisted of never (score 1) with sometimes (score 2) following it, then somewhat (score 3), rarely (score 4), followed by always (score 5).

#### 3. Results

The analysis in Tables 2 through 6 presents findings about scale responses to moral intelligence as well as psychological resilience along with correlation data between scales and gender, college, and age variations. The scores from the moral intelligence test displayed their largest values in conscientiousness (3.61) and their smallest values in respect (2.55) while demonstrating a very strong link to psychological resilience (0.860\*\*). People with religious values demonstrated the highest resilience scores at 3.60, whereas those with social support showed the lowest average at 3.00. These psychological resilience scores positively affected personal and social competence measurements. Women scored higher in justice assessment (3.64) than men (3.53), although men earned better scores in social competence (3.11) compared to women (3.00). College and age did not create noticeable differences. The KMO values revealed proper separation capability (except tolerance: 0.599) between the factors, while chi-square coefficients showed indications of sample size bias. The research outcomes validate theoretical connections between moral elements and psychological constructs by suggesting intervention approaches for specific areas of weakness in social support and respect.

Provides the means and standard deviations from the moral intelligence scale assessment.

60		3.45	0.73	317.79	0.000	
Total		3.59	0.38	419.31	0.000	

Results from the Moral Intelligence Scale indicated that the participants scored 3.24 on average, while conscientiousness (3.613), tolerance (3.622), and justice (3.59) had the highest scores, and respect (2.548) had the lowest score. The KMO values reveal a suitable fit for all axes except for Tolerance (0.599), which requires modification. The statistical chi-square analysis produced only significant results (p=0.000) because the sample contained 386 participants. While Accepting Criticism scored the lowest at 2.22-2.30 in the Respect scale, other Conscientiousness subscales achieved their highest results with Apologizing at 4.08 and Avoiding Insult at 3.88. The analysis indicates that specifically designed interventions must reinforce the identified weak areas.

**Note:** \*Correlation is significant at the 0.05 level. \*\*Correlation is significant at the 0.01 level.

The psychological resilience scale scored a general mean level of 3.21, where the values and religious structure axis (3.60) obtained the highest average responses, but social support (3.00) exhibited the lowest mean score. The KMO values exceeded 0.7 for most axes, yet personal competence stood out with the highest value at 0.840, while social and family competence had the lowest at 0.703. All chi-square values turned out to be significant (p=0.000) due to the large sample size (386) while showing deviations from the expected distribution. The lowest scores appeared in the "support during times of crisis scale" for social support (2.40), yet the highest scores manifested in religious values through the scales "commitment to values" (3.87) and "trust in God's help" (3.67). The outcome shows a need for improved social assistance alongside additional focus on personal competency building.

The study revealed that overall psychological resilience and overall moral intelligence share common traits with a strength of relationship at 0.860\*\*. The analysis revealed that personal competence had a strong positive relationship with respect (0.795\*\*) at the same time social and family competence manifested strong positive links with tolerance (0.985\*\*). These findings indicate how social skills and tolerance foster resilience. Research showed negative relationships between conscientiousness and personal competence (-0.139\*\*), and between religious values and tolerance (0.020, not significant), because these relationships require further research to resolve the discrepancies. The analysis showed the independence of certain dimensions because some relationships were moderate (-0.086 for justice to tolerance) and other relationships showed no significance (0.024 between empathy and respect). Psychological resilience benefits from improving moral elements related to social competence and tolerance based on these research findings.

Independent Samples T-Test to determine the effect of variables gender on the scale of moral intelligence and psychological resilience.

Gender		N	N Mean	Std. Deviation	t	Sig.	95% Confidence Interval of the Difference

	Female	222	3.20	0.27	1.07	0.283	-0.020	0.087

Statistical analysis through the t-test revealed significant score variations between male and female responses for justice (females scored 3.64 while males scored 3.53 with p=0.003) and social and family competence (males showed higher scores at 3.11 while females scored 3.00 with p=0.041), but no other significant differences (p>0.05) were present. The reported statistically significant findings exhibited small magnitude levels with a justice dimension gap of 0.11 and other difference scores under 0.2 (e.g., 0.11 difference in justice). These small effect sizes lessen practical applicability. The observed results indicate possible cultural and social variables (role expectations among others) play a role in creating these gender differences.

The t-test findings revealed no significant differences, ensuring students from scientific and humanities colleges exhibited matching levels of moral intelligence along with psychological resilience dimensions (till personal competence showed marginal significance with p=0.075 yet similar mean values of 3.06 and 3.15). Research findings showed no statistical differences in justice scores (p=0.957) as well as total combined scale scores (p>0.05). The research reveals no strong relationship between college types and personality traits aside from minor variations that need larger participant numbers to verify (religious values: p=0.162). Learning environments and social values between college majors appear similar, which may explain these results, according to the researchers.

One-way ANOVA analysis of variance of participants' scores on moral intelligence and psychological resilience through the age variable.

	Total	29.71	385			

The research results indicated that age differences proved non-significant for moral intelligence skills like empathy (p=0.92) and respect (p=0.71) as well as psychological resilience abilities like social support (p=0.919) and personal competence (p=0.523). However, the participants demonstrated insignificant tolerance variation (p=0.02) that could stem from life experience factors. The level of age influence on variables was found to be weak since tolerance yielded a low F value of 3.18. Age does not substantially affect these traits, according to the research findings.

#### 4. Discussion

The study demonstrated that students exhibited an average level of moral intelligence value possession across every domain of the moral intelligence measure. The students at university level demonstrate strong understanding of right and wrong alongside moral convictions that guide their correct ethical conduct. Higher education institutions play a pivotal role in fostering moral intelligence, which acts as a safeguard against moral decay and helps preserve cultural identity [30]. Through various activities, including academic, cultural, and religious engagements, universities aim to enhance students' abilities to confront challenges that threaten moral values, emphasizing adherence to ethical standards and societal traditions [31]. The establishment of ethics committees and the integration of ethical training into curricula are recommended strategies to reinforce these values [31]. Furthermore, students are encouraged to actively participate in their communities, embodying principles such as honesty, respect, and responsibility, which are essential for personal and collective progress [32]. Thus, the ethical development of students is integral to their role as future leaders and contributors to society.

The results show that universities contribute to enhancing moral intelligence through religious and cultural activities, which enhance conscience and religious values as pillars of moral behavior, but they face challenges in aspects such as respect and weak acceptance of criticism, which heralds a gap between moral slogans and practical application. While students show sensitivity to injustice in justice and the ability to coexist culturally in tolerance, the low level of moral intelligence in anger situations and the difficulty of dealing with new ideas threaten their role as a "moral shield" against decadence. Therefore, universities should strike a balance between instilling religious values and good habits and training students in behavioral skills (such as emotional control and conflict resolution) through practical programs, which turns university students into real actors in preserving the moral identity of society. The studies prove that universities serve as fundamental institutions for developing moral intelligence through religious and cultural activities because students learn essential values of tolerance and empathy [33, 34]. The present study discovered two significant obstacles, namely weak criticism acceptance abilities alongside poor anger regulation skills that threaten the actual use of ethical principles, which aligns with Budiman, et al. [33] findings showing theoretical values' limited practical implementation. Integrated Islamic teaching in educational moral approaches leads to improved moral commitment, according to Romzi, et al. [24] therefore signaling that education needs holistic spiritual training sessions and skill development programs. The training of students in emotional management and conflict resolution stands as a vital component, according to both Lakshmi [35] for dealing with modern-day ethical challenges. Research by Romzi, et al. [24]together with Suharyat, et al. [34] shows that merging religious value enrichment with practical skill development enables students to become "moral agents" in society while protecting social moral identity.

The participants in this study demonstrated average scores across the psychological resilience dimensions consisting of personal competence and social and family competence as well as social support together with values and religious structure. The examination results indicate that psychological resilience shares common components with moral

intelligence through evidence showing emotional regulation capabilities (personal competence) and value-driven approach (religious structure) enable better moral decision-making. Most dimensions of resilience show no meaningful differences based on demographic factors like academic majors and gender leading researchers to believe the development of this trait stems from social and cultural elements rather than inherent personal traits. This confirms that weak social support networks create obstacles to resilience development so universities need to implement interventions to fortify student support resources particularly because social support strongly affects moral crisis endurances. Research results from this study support established scholarly work showing that psychological resilience consists of multiple factors that include personal abilities and social network connections [9, 36]. Personal competence and value-based commitment demonstrate significant alignment with psychological resilience because they both enable effective management of moral dilemmas Rushton [37]. Pan, et al. [38] reveal that individual characteristics might be less important as a factor compared to shared cultural or upbringing influences since demographic data uncovered no major differences in resilience levels. Lack of social support stands as an obstacle whichlimits resilience development making university interventions necessary to strengthen support systems particularly because social support strongly relates to coping with moral challenges [9, 38]. Both personal and social resources need to be developed to promote environments that build resilience according to these findings.

The study findings revealed that moral intelligence leads to psychological resilience because both variables demonstrate positive relationships. The studies emphasize dimensions such as respect, empathy, and self-control as key predictors of resilience, particularly among university students [39, 40]. Empirical evidence suggests that individuals with higher moral intelligence employ adaptive coping mechanisms, which synergize with psychological resilience to enhance their ability to navigate challenges effectively [37, 41]. Notably, moral resilience—defined as the capacity to uphold ethical integrity amid moral adversity—has been linked to improved mental health outcomes and reduced burnout, especially in high-stress professions such as nursing [41]. This interplay underscores the imperative to integrate moral education into academic and professional training programs. By fostering moral intelligence and resilience, institutions can cultivate individuals who not only thrive psychologically but also contribute to societal well-being through ethically grounded decision-making [39, 40]. Such integration aligns with broader goals of promoting mental health and ethical leadership in response to contemporary societal challenges.

#### 5. Conclusions

This study highlights the significant role of moral intelligence in strengthening psychological resilience among students at King Faisal University, Saudi Arabia. Students who display higher moral intelligence levels present better psychological resilience because their ethical character traits of empathy and conscientiousness and justice traits promote adaptive capabilities. Higher moral intelligence leads students to develop better coping abilities as research confirms that resilience serves as a protective factor in demanding situations [39, 41]. The participants displayed successful conscientiousness and tolerance, but their inadequate respect scores indicate fundamental problems in managing criticism as well as building respectful communication. The data matches up with educational and cultural barriers for developing positive interpersonal exchanges. The high scores in religious and value-based assessments underline the successful adoption of Islamic faith by students which both develops internal ethical principles and enhances personal integrity. Research has established how religion serves as a resilience-enhancing factor within cultural contexts that can be classified as collectivist [24]. The mixed results from social support and personal competence assessments show students require both educational institutions and community networks to build better peer relationships and stress-coping skills to face future professional life.

#### 5.1. Implications for Universities

Education programs for moral instruction should be integrated into curriculum to teach respect alongside conflict resolution and emotional self-control techniques. To fill psychological resilience gaps, universities require improvement of their social support systems through services like counseling as well as mentorship opportunities. The research by Baraka et al. (2024) reveals that Islamic principles should be utilized to both support ethical choices and moral durability in students.

## 5.2. Future Research

Future research requires multiple time-point investigations to track how moral intelligence and resilience develop throughout educational levels between different cultures. The examination of gender distinctions together with disciplinary patterns would help enhance specific intervention methods. Results from this study improve knowledge about the interdependent nature of moral intelligence and resilience in Saudi higher education while providing practical guidelines for developing ethical future leaders.5.2. Implications for Educational Institutions:
